11. Media Scrutiny (rank)	63	11. Media Scrutiny (rank)	
12. Conflict (score)	2.60	12. Conflict (score)	
12. Conflict (rank)	81	12. Conflict (rank)	
1.0 - Aridity (score)	1.00	The aridity risk indicator is based on the Global Aridity Index (Global-Aridity) and Global Potential Evapo-Transpiration (Global-PET) Geospatial data sets by Trabucco and Zomer (2009). These data sets provide information about the potential availability of water in regions with low water demand, thus they are used in the Water Risk Filter 5.0 to better account for deserts and other arid areas in the risk assessment.	Trabucco, A., & Zomer, R. J. (2009). Global potential evapo-transpiration (Global-PET) and global aridity index (Global-Aridity) geodatabase. CGIAR consortium for spatial information.
1.0 - Aridity (rank)	163	The aridity risk indicator is based on the Global Aridity Index (Global-Aridity) and Global Potential Evapo-Transpiration (Global-PET) Geospatial data sets by Trabucco and Zomer (2009). These data sets provide information about the potential availability of water in regions with low water demand, thus they are used in the Water Risk Filter 5.0 to better account for deserts and other arid areas in the risk assessment.	Trabucco, A., & Zomer, R. J. (2009). Global potential evapo-transpiration (Global-PET) and global aridity index (Global-Aridity) geodatabase. CGIAR consortium for spatial information.
1.1 - Water Depletion (score)	2.06	The water depletion risk indicator is based on annual average monthly net water depletion from Brauman et al. (2016). Their analysis is based on model outputs from the newest version of the integrated water resources model WaterGAP3 which measures water depletion as the ratio of water consumption-to-availability.	Brauman, K. A., Richter, B. D., Postel, S., Malsy, M., & Flörke, M. (2016). Water depletion: An improved metric for incorporating seasonal and dry-year water scarcity into water risk assessments. <i>Elem Sci Anth</i> , 4.
1.1 - Water Depletion (rank)	81	The water depletion risk indicator is based on annual average monthly net water depletion from Brauman et al. (2016). Their analysis is based on model outputs from the newest version of the integrated water resources model WaterGAP3 which measures water depletion as the ratio of water consumption-to-availability.	Brauman, K. A., Richter, B. D., Postel, S., Malsy, M., & Flörke, M. (2016). Water depletion: An improved metric for incorporating seasonal and dry-year water scarcity into water risk assessments. <i>Elem Sci Anth</i> , 4.
1.2 - Baseline Water Stress (score)	1.99	World Resources Institute's Baseline Water Stress measures the ratio of total annual water withdrawals to total available annual renewable supply, accounting for upstream consumptive use. A higher percentage indicates more competition among users.	Hofste, R., Kuzma, S., Walker, S., ... & Sutanudjaja, E.H. (2019). <i>Aqueduct 3.0: Updated decision relevant global water risk indicators</i> . Technical note. Washington, DC: World Resources Institute.

Country Overview - Netherlands

Indicator	Value	Description	Source
1.2 - Baseline Water Stress (rank)	91	World Resources Institute's Baseline Water Stress measures the ratio of total annual water withdrawals to total available annual renewable supply, accounting for upstream consumptive use. A higher percentage indicates more competition among users.	Hofste, R., Kuzma, S., Walker, S., ... & Sutanudjaja, E.H. (2019). Aqueduct 3.0: Updated decision relevant global water risk indicators. Technical note. Washington, DC: World Resources Institute.
1.3 - Blue Water Scarcity (score)	1.98	The blue water scarcity risk indicator is based on Mekonnen and Hoekstra (2016) global assessment of blue water scarcity on a monthly basis and at high spatial resolution (grid cells of 30 × 30 arc min resolution). Blue water scarcity is calculated as the ratio of the blue water footprint in a grid cell to the total blue water availability in the cell. The time period analyzed in this study ranges from 1996 to 2005.	Mekonnen, M. M., & Hoekstra, A. Y. (2016). Four billion people facing severe water scarcity. <i>Science advances</i> , 2(2), e1500323.
1.3 - Blue Water Scarcity (rank)	125	The blue water scarcity risk indicator is based on Mekonnen and Hoekstra (2016) global assessment of blue water scarcity on a monthly basis and at high spatial resolution (grid cells of 30 × 30 arc min resolution). Blue water scarcity is calculated as the ratio of the blue water footprint in a grid cell to the total blue water availability in the cell. The time period analyzed in this study ranges from 1996 to 2005.	Mekonnen, M. M., & Hoekstra, A. Y. (2016). Four billion people facing severe water scarcity. <i>Science advances</i> , 2(2), e1500323.
1.4 - Projected Change in Water Discharge (by ~2050) (score)	1.56	This risk indicator is based on multi-model simulation that applies both global climate and hydrological models from the Inter-Sectoral Impact Model Intercomparison Project (ISIMIP). To estimate the change at 2°C of global warming above 1980-2010 levels, simulated annual water discharge was averaged over a 31-year period with 2°C mean warming. Results are expressed in terms of relative change (%) in probability between present day (1980-2010) conditions and 2°C scenarios by 2050.	Schewe, J., Heinke, J., Gerten, D., Haddeland, I., Arnell, N. W., Clark, D. B., ... & Gosling, S. N. (2014). Multimodel assessment of water scarcity under climate change. <i>Proceedings of the National Academy of Sciences</i> , 111(9), 3245-3250.
1.4 - Projected Change in Water Discharge (by ~2050) (rank)	128	This risk indicator is based on multi-model simulation that applies both global climate and hydrological models from the Inter-Sectoral Impact Model Intercomparison Project (ISIMIP). To estimate the change at 2°C of global warming above 1980-2010 levels, simulated annual water discharge was averaged over a 31-year period with 2°C mean warming. Results are expressed in terms of relative change (%) in probability between present day (1980-2010) conditions and 2°C scenarios by 2050.	Schewe, J., Heinke, J., Gerten, D., Haddeland, I., Arnell, N. W., Clark, D. B., ... & Gosling, S. N. (2014). Multimodel assessment of water scarcity under climate change. <i>Proceedings of the National Academy of Sciences</i> , 111(9), 3245-3250.

Country Overview - Netherlands

Indicator	Value	Description	Source
1.5 - Drought Frequency Probability (score)	1.75	This risk indicator is based on the Standardized Precipitation and Evaporation Index (SPEI). Vicente-Serrano et al. (2010) developed this multi-scalar drought index applying both precipitation and temperature data to detect, monitor and analyze different drought types and impacts in the context of global warming. The mathematical calculations used for SPEI are similar to the Standard Precipitation Index (SPI), but it has the advantage to include the role of evapotranspiration.	Vicente-Serrano, S. M., Beguería, S., & López-Moreno, J. I. (2010). A multiscale drought index sensitive to global warming: the standardized precipitation evapotranspiration index. <i>Journal of climate</i> , 23(7), 1696-1718.
1.5 - Drought Frequency Probability (rank)	162	This risk indicator is based on the Standardized Precipitation and Evaporation Index (SPEI). Vicente-Serrano et al. (2010) developed this multi-scalar drought index applying both precipitation and temperature data to detect, monitor and analyze different drought types and impacts in the context of global warming. The mathematical calculations used for SPEI are similar to the Standard Precipitation Index (SPI), but it has the advantage to include the role of evapotranspiration.	Vicente-Serrano, S. M., Beguería, S., & López-Moreno, J. I. (2010). A multiscale drought index sensitive to global warming: the standardized precipitation evapotranspiration index. <i>Journal of climate</i> , 23(7), 1696-1718.
1.6 - Projected Change in Drought Occurrence (by ~2050) (score)	3.00	This risk indicator is based on multi-model simulation that applies both global climate and drought models from the Inter-Sectoral Impact Model Intercomparison Project (ISIMIP) . A drought threshold for pre-industrial conditions was calculated based on time-series averages. Results are expressed in terms of relative change (%) in probability between pre-industrial and 2°C scenarios.	Frieler, K., Lange, S., Piontek, F., Reyer, C. P., Schewe, J., Warszawski, L., ... & Geiger, T. (2017). Assessing the impacts of 1.5 C global warming-simulation protocol of the Inter-Sectoral Impact Model Intercomparison Project (ISIMIP2b). Geoscientific Model Development.
1.6 - Projected Change in Drought Occurrence (by ~2050) (rank)	136	This risk indicator is based on multi-model simulation that applies both global climate and drought models from the Inter-Sectoral Impact Model Intercomparison Project (ISIMIP) . A drought threshold for pre-industrial conditions was calculated based on time-series averages. Results are expressed in terms of relative change (%) in probability between pre-industrial and 2°C scenarios.	Frieler, K., Lange, S., Piontek, F., Reyer, C. P., Schewe, J., Warszawski, L., ... & Geiger, T. (2017). Assessing the impacts of 1.5 C global warming-simulation protocol of the Inter-Sectoral Impact Model Intercomparison Project (ISIMIP2b). Geoscientific Model Development.
2.1 - Estimated Flood Occurrence (score)	2.99	This risk indicator is based on the recurrence of floods within the 34-year time frame period of 1985 to 2019. The occurrence of floods within a given location was estimated using data from Flood Observatory, University of Colorado. The Flood Observatory use data derived from a wide variety of news, governmental, instrumental, and remote sensing source.	Brakenridge, G. R. (2019). Global active archive of large flood events. Dartmouth Flood Observatory, University of Colorado.
2.1 - Estimated Flood Occurrence (rank)	117	This risk indicator is based on the recurrence of floods within the 34-year time frame period of 1985 to 2019. The occurrence of floods within a given location was estimated using data from Flood Observatory, University of Colorado. The Flood Observatory use data derived from a wide variety of news, governmental, instrumental, and remote sensing source.	Brakenridge, G. R. (2019). Global active archive of large flood events. 2.2 - Projected Change in Flood Occurrence (by ~2050) (score)	3.00	This risk indicator is based on multi-model simulation that applies both global climate and drought models from the Inter-Sectoral Impact Model Intercomparison Project (ISIMIP). The magnitude of the flood event was defined based on 100-year return period for pre-industrial conditions. Results are expressed in terms of change (%) in probability between pre-industrial and 2°C scenarios.	Frieler, K., Lange, S., Piontek, F., Reyer, C. P., Schewe, J., Warszawski, L., ... & Geiger, T. (2017). Assessing the impacts of 1.5 C global warming-simulation protocol of the Inter-Sectoral Impact Model Intercomparison Project (ISIMIP2b). Geoscientific Model Development.
2.2 - Projected Change in Flood Occurrence (by ~2050) (rank)	44	This risk indicator is based on multi-model simulation that applies both global climate and drought models from the Inter-Sectoral Impact Model Intercomparison Project (ISIMIP). The magnitude of the flood event was defined based on 100-year return period for pre-industrial conditions. Results are expressed in terms of change (%) in probability between pre-industrial and 2°C scenarios.	Frieler, K., Lange, S., Piontek, F., Reyer, C. P., Schewe, J., Warszawski, L., ... & Geiger, T. (2017). Assessing the impacts of 1.5 C global warming-simulation protocol of the Inter-Sectoral Impact Model Intercomparison Project (ISIMIP2b). Geoscientific Model Development.
3.1 - Surface Water Contamination Index (score)	4.15	<p>The underlying data for this risk indicator is based on a broad suite of pollutants with well-documented direct or indirect negative effects on water security for both humans and freshwater biodiversity, compiled by Vörösmarty et al. (2010). The negative effects are specific to individual pollutants, ranging from impacts mediated by eutrophication such as algal blooms and oxygen depletion (e.g., caused by phosphorus and organic loading) to direct toxic effects (e.g., caused by pesticides, mercury).</p> <p>The overall Surface Water Contamination Index is calculated based on a range of key pollutants with different weightings according to the level of their negative effects on water security for both humans and freshwater biodiversity: soil salinization (8%), nitrogen (12%) and phosphorus (P, 13%) loading, mercury deposition (5%), pesticide loading (10%), sediment loading (17%), organic loading (as Biological Oxygen Demand, BOD; 15%), potential acidification (9%), and thermal alteration (11%).</p>	Vörösmarty, C. J., McIntyre, P. B., Gessner, M. O., Dudgeon, D., Prusevich, A., Green, P., ... & Davies, P. M. (2010). Global threats to human water security and river biodiversity. <i>Nature</i> , 467(7315), 555.

Indicator	Value	Description	Source
3.1 - Surface Water Contamination Index (rank)	15	<p>The underlying data for this risk indicator is based on a broad suite of pollutants with well-documented direct or indirect negative effects on water security for both humans and freshwater biodiversity, compiled by Vörösmarty et al. (2010). The negative effects are specific to individual pollutants, ranging from impacts mediated by eutrophication such as algal blooms and oxygen depletion (e.g., caused by phosphorus and organic loading) to direct toxic effects (e.g., caused by pesticides, mercury).</p> <p>The overall Surface Water Contamination Index is calculated based on a range of key pollutants with different weightings according to the level of their negative effects on water security for both humans and freshwater biodiversity: soil salinization (8%), nitrogen (12%) and phosphorus (P, 13%) loading, mercury deposition (5%), pesticide loading (10%), sediment loading (17%), organic loading (as Biological Oxygen Demand, BOD; 15%), potential acidification (9%), and thermal alteration (11%).</p>	Vörösmarty, C. 4.1 - Fragmentation Status of Rivers (score)	3.36	<p>This risk indicator is based on the data set by Grill et al. (2019) mapping the world's free-flowing rivers. Grill et al. (2019) compiled a geometric network of the global river system and associated attributes, such as hydro-geometric properties, as well as pressure indicators to calculate an integrated connectivity status index (CSI). While only rivers with high levels of connectivity in their entire length are classified as free-flowing, rivers of CSI < 95% are considered as fragmented at a certain degree.</p>	Grill, G., Lehner, B., Thieme, M., Geenen, B., Tickner, D., Antonelli, F., ... & Macedo, H. E. (2019). Mapping the world's free-flowing rivers. <i>Nature</i> , 569(7755), 215.
4.1 - Fragmentation Status of Rivers (rank)	39	<p>This risk indicator is based on the data set by Grill et al. (2019) mapping the world's free-flowing rivers. Grill et al. (2019) compiled a geometric network of the global river system and associated attributes, such as hydro-geometric properties, as well as pressure indicators to calculate an integrated connectivity status index (CSI). E. (2019). Mapping the world's free-flowing rivers. <i>Nature</i> , 569(7755), 215.
4.2 - Catchment Ecosystem Services Degradation Level (tree cover loss) (score)	1.17	<p>For this risk indicator, tree cover loss was applied as a proxy to represent catchment ecosystem services degradation since forests play an important role in terms of water regulation, supply and pollution control. The forest cover data is based on Hansen et al.'s global Landsat data at a 30-meter spatial resolution to characterize forest cover and change. The authors defined trees as vegetation taller than 5 meters in height, and forest cover loss as a stand-replacement disturbance, or a change from a forest to non-forest state, during the period 2000 – 2018.</p>	Hansen, M. C., Potapov, P. V., Moore, R., Hancher, M., Turubanova, S. A. A., Tyukavina, A., ... & Kommareddy, A. (2013). High-resolution global maps of 21st-century forest cover change. <i>science</i> , 342(6160), 850-853.

5.1 - Freshwater Policy Status (SDG 6.5.1) (score)	1.00	This risk indicator is based on SDG 6.5.1. Degree of IWRM Implementation "National Water Resources Policy" indicator, which corresponds to one of the three national level indicators under the Enabling Environment category.	UN Environment (2018). Progress on integrated water resources management. Global baseline for SDG 6 Indicator 6.5.1: degree of IWRM implementation.
5.1 - Freshwater Policy Status (SDG 6.5.1) (rank)	185	This risk indicator is based on SDG 6.5.1. Degree of IWRM Implementation "National Water Resources Policy" indicator, which corresponds to one of the three national level indicators under the Enabling Environment category.	UN Environment (2018). Progress on integrated water resources management. Global baseline for SDG 6 Indicator 6.5.1: degree of IWRM implementation.
5.2 - Freshwater Law Status (SDG 6.5.1) (score)	1.00	<p>This risk indicator is based on SDG 6.5.1. Degree of IWRM Implementation "National Water Resources Law(s)" indicator, which corresponds to one of the three national level indicators under the Enabling Environment category.</p> <p>For SDG 6.5.1, enabling environment depicts the conditions that help to support the implementation of IWRM, which includes legal and strategic planning tools for IWRM.</p>	UN Environment (2018). Progress on integrated water resources management. Global baseline for SDG 6 Indicator 6.5.1: degree of IWRM implementation.

Indicator	Value	Description	Source
6.2 - Freedom in the World Index (rank)	172	This risk indicator is based on Freedom House (2019), an annual global report on political rights and civil liberties, composed of numerical ratings and descriptive texts for each country and a select group of territories. The 2019 edition involved more than 100 analysts and more than 30 advisers with global, regional, and issue-based expertise to covers developments in 195 countries and 14 territories from January 1, 2018, through December 31, 2018.	Freedom House (2019). Freedom in the world 2019. Washington, DC: Freedom House.
6.3 - Business Participation in Water Management (SDG 6.5.1) (score)	1.00	This risk indicator is based on SDG 6.5.1. Degree of IWRM Implementation "Business Participation in Water Resources Development, Management and Use" indicator, which corresponds to one of the six national level indicators under the Institutions and Participation category.	UN Environment (2018). Progress on integrated water resources management. Global baseline for SDG 6 Indicator 6.5.1: degree of IWRM implementation.
6.3 - Business Participation in Water Management (SDG 6.5.1) (rank)	180	This risk indicator is based on SDG 6.5.1. Degree of IWRM Implementation "Business Participation in Water Resources Development, Management and Use" indicator, which corresponds to one of the six national level indicators under the Institutions and Participation category.	UN Environment (2018). Progress on integrated water resources management. Global baseline for SDG 6 Indicator 6.5.1: degree of IWRM implementation.
7.1 - Management Instruments for Water Management (SDG 6.5.1) (score)	1.00	This risk indicator is based on SDG 6.5.1. Degree of IWRM Implementation "Sustainable and efficient water use management" indicator, which corresponds to one of the five national level indicators under the Management Instruments category. For SDG 6.5.1, management instruments refer to the tools and activities that enable decision-makers and users to make rational and informed choices between alternative actions.	UN Environment (2018). Progress on integrated water resources management. Global baseline for SDG 6 Indicator 6.5.1: degree of IWRM implementation.
7.1 - Management Instruments for Water Management (SDG 6.5.1) (rank)	180	This risk indicator is based on SDG 6.5.1. Degree of IWRM Implementation "Sustainable and efficient water use management" indicator, which corresponds to one of the five national level indicators under the Management Instruments category. Indicator	Value	Description	Source
7.2 - Groundwater Monitoring Data Availability and Management (score)	1.00	This risk indicator is based on the data set by UN IGRAC (2019) to determine the level of availability of groundwater monitoring data at country level as groundwater management decisions rely strongly on data availability. The level of groundwater monitoring data availability for groundwater management is determined according to a combination of three criteria developed by WWF and IGRAC: 1) Status of country groundwater monitoring programme, 2) groundwater data availability for NGOs and 3) Public access to processed groundwater monitoring data.	UN IGRAC (2019). Global Groundwater Monitoring Network GGMM Portal. UN International Groundwater Resources Assessment Centre (IGRAC).
7.2 - Groundwater Monitoring Data Availability and Management (rank)	178	This risk indicator is based on the data set by UN IGRAC (2019) to determine the level of availability of groundwater monitoring data at country level as groundwater management decisions rely strongly on data availability. The level of groundwater monitoring data availability for groundwater management is determined according to a combination of three criteria developed by WWF and IGRAC: 1) Status of country groundwater monitoring programme, 2) groundwater data availability for NGOs and 3) Public access to processed groundwater monitoring data.	UN IGRAC (2019). Global Groundwater Monitoring Network GGMM Portal. UN International Groundwater Resources Assessment Centre (IGRAC).
7.3 - Density of Runoff Monitoring Stations (score)	2.23	The density of monitoring stations for water quantity was applied as proxy to develop this risk indicator. The Global Runoff Data Base was used to estimate the number of monitoring stations per 1000km ² of the main river system (data base access date: May 2018).	BfG (2019). Global Runoff Data Base. German Federal Institute of Hydrology (BfG).
7.3 - Density of Runoff Monitoring Stations (rank)	159	The density of monitoring stations for water quantity was applied as proxy to develop this risk indicator. The Global Runoff Data Base was used to estimate the number of monitoring stations per 1000km ² of the main river system (data base access date: May 2018).	BfG (2019). Global Runoff Data Base. German Federal Institute of Hydrology (BfG).
8.1 - Access to Safe Drinking Water (score)	1.00	This risk indicator is based on the Joint Monitoring Programme for Water Supply, Sanitation and Hygiene (UNICEF/WHO) 2019 data. It provides estimates on the use of water, sanitation and hygiene by country for the period 2000-2017.	WHO & UNICEF (2019). Estimates on the use of water, sanitation and hygiene by country (2000-2017). Joint Monitoring Programme for Water Supply, Sanitation and Hygiene.
8.1 - Access to Safe Drinking Water (rank)	167	This risk indicator is based on the Joint Monitoring Programme for Water Supply, Sanitation and Hygiene (UNICEF/WHO) 2019 data. It provides estimates on the use of water, sanitation and hygiene by country for the period 2000-2017.	WHO & UNICEF (2019). Estimates on the use of water, sanitation and hygiene by country (2000-2017). Joint Monitoring Programme for Water Supply, Sanitation and Hygiene.
8.2 - Access to Sanitation (score)	1.00	This risk indicator is based on the Joint Monitoring Programme for Water Supply, Sanitation and Hygiene (UNICEF/WHO) 2019 data. It provides estimates on the use of water, sanitation and hygiene by country for the period 2000-2017.	WHO & UNICEF (2019). Estimates on the use of water, sanitation and hygiene by country (2000-2017). Joint Monitoring Programme for Water Supply, Sanitation and Hygiene.

Country Aspects

1. PHYSICAL ASPECTS

1.1. WATER RESOURCES

1.1.1. WATER RESOURCES

Average annual precipitation in the Netherlands is 778mm. Average annual renewable water resources stand at 910 million km³. Only 11 per cent of this is internal water resources (110 million km³) while as much as 89 per cent is external water resources (800 million km³). In 2009, the total dam (reservoir) capacity was 92.34 million km³.

The Netherlands has four river basin districts (RBDs), all of which are international shared watercourses with Belgium, France, Luxembourg and Germany. They are: the Meuse RBD, the Ems RBD, the Scheldt RBD and the Rhine RBD. Consultation on draft River Basin Management Plans took place between December 2008 and June 2009. They were adopted in December 2009.

1.1.2. WATER USE

The availability of water and well-functioning freshwater ecosystems are essential to people and nature. Large-scale groundwater use is one of the causes of the degradation of nature in the Netherlands.

Estimated water withdrawal is 106.1 million km³/yr, of which only 9.67 million km³ (9 per cent) comes from groundwater sources. The remaining 91 per cent is abstracted from surface water bodies (up to 96.4 million km³). By 2008, it was estimated that water for urban areas made up 12.5 million km³ (around 12 per cent) of total consumption. Only an estimated 71 million m³ of water was used for agriculture. The vast majority of water consumed – 87 per cent of the total, or 92.83 million km³ – was for industrial uses. Use of freshwater systems for drinking water, shipping, industrial intakes and all other uses has been at constant levels during the past 30 years.

Due to the expected impacts of climate change, current strategies to cope with water shortages and fresh water supply in the Netherlands need to be revised. This is very complex because of the combination of technical and social aspects (for example, the relationship between different regions within the Netherlands), the relationship between the so-called regional goals and regional usages of water, and the consequences of the national strategy for river water discharge. In addition, it is expected that the demand for water will increase and precipitation in summer will decrease, thus the availability (and level of security in the supply) of fresh water will likely decrease if no action is taken. The degree of this decrease will vary from region to region. Not only will this impact the water level of rivers and ditches, and therefore overall water levels, it will also have consequences for agriculture, inland shipping, nature and water quality. Due to higher water temperatures, the amount of algae will increase.

1.2. WATER QUALITY, ECOSYSTEMS AND HUMAN HEALTH

Much environmental pressure comes from the production sectors of agriculture, industry, energy and transport. In the Netherlands, over 80 per cent of CO₂ and NO_x emissions come from these production processes. Almost 80 per cent of the acidifying emissions and over 50 per cent of greenhouse gas emissions come from these sectors, which in total contribute less than 10 per cent to the country's GDP. The performance of the service sector has been different. This sector generates almost 70 per cent of GDP but causes little direct environmental pressure. It should be noted, however, that the service sector would not be able to function without input from the agricultural, energy and transport sectors.

Water pressures at national level are partly from outside sources. Intrusion of salt water from the sea in waterways and groundwater affects the quality of water, as well as its application in agriculture. Sources from neighbouring upstream countries also cause pollution (nutrients and other compounds) of the large rivers Rhine, Meuse and Scheldt.

The main pressures for the smaller inland surface waters and groundwater are agriculture, urban wastewater treatment plants (UWWTP) and industry. The pressure from UWWTP and industry has decreased considerably in the past years. In 2007, nearly 98 per cent of domestic wastewater and 93 per cent of industrial wastewater was treated in UWWTP. At large industrial sites, the wastewater is often treated in private treatment plants. The efficiency of the treatment of N and P (Nitrogen and Phosphorous) at UWWTP increased from about 40 per cent in 1981 to about 80 per cent in 1997. For N in particular the increase was due to the requirements of the EU Directive on Urban Wastewater.

As a result of the European Nitrate Directive, the nitrogen surplus in Dutch agriculture decreased by almost 40 per cent between 1992 and 2007. The average nitrate concentration during the winter period in fresh surface waters has been decreasing since 1998. Both nitrate content and eutrophication are decreasing. However, it takes several years before the effects of policy measures taken by farmers are seen in the water quality. It is therefore expected that it will be some years before the effects of recent policy measures from the 2004-2009 action programme are seen in water quality.

The implementation of Water Framework Directive (WFD) measures is expected to result in good water condition in about a quarter of all water bodies by 2015. For the remaining three-quarters, this will happen after 2015. It is expected that the concentration of nitrate in groundwater will improve, but not enough to meet the standard (50mg/L) in 2027. Also, by 2027, surface waters are expected to reach approximately 40 to 60 per cent of the WFD EU standards for N and P. This is also the case for the ecological quality of regional waters. Because EU targets are not expected to be met by 2015, there will be a phasing to 2027 (time exemptions).

Currently the 30-40 per cent ecological quality of surface waters exceeds WFD standards, because

of high concentrations of phosphorus, nitrate, and pesticides, among other things. Water temperature is of growing concern. The number of water intake stops during summer periods is growing, creating significant problems for water cooling plants. Also, the use of fresh water to produce drinking water is hampered by chemical substances, such as pesticides and hormone disrupters.

2. GOVERNANCE ASPECTS

2.1. WATER INSTITUTIONS

Until October 2010, the Ministry of Housing, Spatial Planning and the Environment (VROM), and more specifically the Directorate-General (DG) Environment, developed and implemented environmental policy in the Netherlands. VROM's mission was to establish favourable conditions for pleasant living, working, recreation and transportation in the Netherlands. To achieve this, the Ministry developed regulations and consulted the population, actively seeking involvement of citizens and business representatives in establishing rules and regulations. In October 2010, DG Environment and the Ministry of Transport and Water Management merged into the new Ministry of Infrastructure and Environment.

2.2. WATER MANAGEMENT

The Dutch Ministry of Infrastructure and Environment cooperates closely with international governments and administrations at regional and municipal levels. Nevertheless, the Dutch government decides on national issues as a rule of thumb. Provincial and municipal councils have their own decision-making powers at regional and local levels. National policy naturally restricts the powers of these local administrations.

A key principle, however, is to keep decision-making powers as close as possible to the local level, promoting participative democracy. Large parts of national environmental policy have been decentralized. This means, for instance, that provincial councils are responsible for executing national policies on waste and groundwater management, and for providing environmental permits for large companies. District water boards are responsible for wastewater treatment and chemical and ecological water quality. Municipal councils are responsible for national policies on public safety, noise, odour and local air quality. Generally speaking, enforcement of environmental rules and regulations has largely been allocated to the municipalities.

The integration of environmental regulations into policies and regulations of other ministries, such as those of the Ministry of Economic Affairs (innovation policy, energy conservation, renewable energy); the Ministry of Agriculture, Nature and Food Quality (policies on manure, agro-chemicals, groundwater, nature conservation) is also a priority.

Dutch water safety policy starts with a basic safety level for each citizen, a socially acceptable risk for large groups of people, and an economically optimal safety level. The Netherlands' policy plans focus on reducing the chances of flooding from the sea (for example, through coastal defence systems) and from rivers. Retaining more water in inland water basins will help with the latter. The

large rivers will be adjusted to be able to manage the larger outflows which are expected in the future.

To protect water quality, river basin management plans (Stroomgebiedbeheerplannen, SGBPs) lay down nearly 3,000 national and regional measures. Regional and national plans have provided the building blocks. The SGBPs state the current water quality for each basin area, as well as the objectives for improving this quality and their corresponding measures. The Netherlands is combining two approaches to improve water quality: dealing with substances at their source, and improving the organization of water systems.

Two programmes already implemented to deal with water quality issues are the High Water Protection Programme (Hoogwaterbeschermingsprogramma, HWBP), which deals with primary dyke reinforcements and drainage systems; and Room for the River (Ruimte voor de Rivier), which encompasses around 40 large-scale measures to protect river basin areas against flooding. These vary from digging out riparian meadows and dyke displacement to lowering groynes and enlarging summer riverbeds. For the Meuse River, measures will be taken to protect against high water, whereby the river is deepened and widened, combined with flood channels, retention basins and dyke reinforcements.

In 2008 water board taxes changed. Three new fees have been created:

- A so-called "water system fee" to ensure "dry feet and a clean freshwater supply";
- A purification fee, to ensure treatment of wastewater;
- A pollution fee to allow discharges directly into freshwater.

2.3. WATER POLICY AND LEGAL FRAMEWORK

The main directives and legislation at the European level related to water resources management are:

- Directive 80/68/EEC of 17 December, 1979 on the protection of groundwater against pollution caused by certain dangerous substances;
- Directive 82/176/EEC of 22 March, 1982 on limit values and quality objectives for mercury discharges by the chlor-alkali electrolysis industry; covers inland surface water, territorial waters and internal coastal waters;
- Directive 83/513/EEC of 26 September, 1983 on limit values and quality objectives for cadmium discharges; sets limit values and quality objectives for cadmium discharges in the aquatic environment;
- Directive 84/156/EEC of 8 March, 1984 on limit values and quality objectives for mercury discharges by sectors other than the chlor-alkali electrolysis industry; sets limit values and quality objectives for mercury discharges in sectors other than the chlor-alkali electrolysis industry;
- Directive 84/491/EEC of 9 October, 1984 on limit values and quality objectives for discharges of hexachlorocyclohexane;
- Directive 91/271/EEC of 21 May, 1991 concerning urban waste water treatment;
- Directive 91/676/EEC of 12 December, 1991 concerning the protection of waters against pollution caused by nitrates from agricultural sources (known as the Nitrates Directive);

- Directive 98/83/EC of 3 November, 1998 on the quality of water;
- Directive 2000/60/EC of the European Parliament and of the Council establishing a framework for the Community action in the field of water policy;
- Regulation (EC) No 648/2004 of the European Parliament and of the Council of 31 March, 2004 on detergents;
- Decision 2006/507/EC of 14 October, 2004 concerning the conclusion, on behalf of the European Community, of the Stockholm Convention on Persistent Organic Pollutants (POPs);
- Directive 2006/7/EC of the European Parliament and of the Council of 15 February, 2006 concerning the management of bathing water quality and repealing Directive 76/160/EEC (with effect from 31 December, 2014);
- Directive 2006/44/EC of 6 September, 2006 on the quality of fresh waters needing protection or improvement in order to support fish life (this Directive will be repealed by the Framework Directive on water as of the end of 2013);
- Directive 2006/11/EC of the European Parliament and of the Council of 15 February, 2006 on pollution caused by certain dangerous substances discharged into the aquatic environment of the Community the European Union (this Directive will be repealed by the Framework Directive on water as of the end of 2013);
- Proposal for a European Parliament and Council Directive of 22 September, 2006 setting out a framework for soil protection and amending Council Directive 2004/35/EC [COM (2006) 231 final – not published in the Official Journal];
- Directive 2006/118/EC of the European Parliament and of the Council of 12 December, 2006 on the protection of groundwater against pollution and deterioration;
- Directive 2007/2/EC of the European Parliament and of the Council of 14 March, 2007 establishing an Infrastructure for Spatial Information in the European Community (INSPIRE);
- Commission Communication of 18 July, 2007: “Addressing the challenge of water scarcity and droughts in the European Union” [COM (2007) 414 final – not published in the Official Journal];
- Directive 2007/60/EC of the European Parliament and of the Council of 23 October, 2007 on the assessment and management of flood risks; aims to manage and reduce the risk of floods, particularly along rivers and in coastal areas;
- Directive 2008/1/EC of the European Parliament and of the Council of 15 January 2008 concerning integrated pollution prevention and control (the IPPC Directive);
- Directive 2009/28/EC on the promotion of the use of energy from renewable sources and amending and subsequently repealing Directives 2001/77/EC and 2003/30/EC.

As an EU Member State, the Netherlands has to implement this legislation in its own legal framework, defining specific laws for the implementation of the different directives and the common legislative principles. This is the Ministry of Infrastructure and Environment's responsibility.

3. GEOPOLITICAL ASPECT

Compared to other European countries, environmental pressure in the Netherlands is high. This is

not surprising, given the demographic and socio-economic characteristics of the country. It has a high population density, with a large degree of urbanization, a large share of heavy and energy-intensive industry, and is a major exporter of agricultural and other products. The Dutch economy is closely connected to those of other countries. The Netherlands is also in a low-lying river delta, which creates environmental pressure. Moreover, the country plays an important role in transporting and distributing goods within Europe. The Netherlands is one of the most densely populated European countries when expressed in number of inhabitants, with the largest numbers of livestock, and the most industry and cars per square kilometre.

Since environmental pressure per square kilometre is high, the Netherlands takes more environmental measures, on average, than other EU countries. This applies to cogeneration (power stations), use of advanced wastewater treatment technology, and of flue gas cleaning systems in industry. The Netherlands is and remains an energy-intensive economy. However, the eco-efficiency of the economy has improved. In a scenario with moderate economic growth and strong (international) environmental policy, this trend will likely continue.

With respect to the protection of nature, all Natura 2000 areas within the Netherlands are interconnected. Approximately 30 per cent of natural areas are protected against excessive nitrogen deposition, which is similar to the average protection rate within the EU. In 2010 it was estimated that over 70 per cent of Dutch nature areas would be at risk of acidification. This is significantly higher than the 11 per cent for the other EU countries. For the Netherlands, it is relatively expensive to meet EU obligations, as they have to take more measures to reduce pollution, generally, than other EU countries.

In the 1970s, environmental policy in the Netherlands – as in many other western countries – was more or less nationally aimed. In the late 1980s, the Netherlands had become a leader in the field of environmental policy. A clean environment was seen as a prerequisite for a healthy economy; a clean economy was seen as an efficient economy. Later on, a shift took place from the use of end-of-pipe technologies to an integrated approach where various environmental issues were solved in combination. Other directorates also took environmental considerations into account in their policies.

The 1988 publication of the first environmental outlook *Concerns for Tomorrow* by the National Institute for Public Health and the Environment (RIVM) can be regarded as an important occasion. The Dutch government was preparing its first National Environmental Policy Plan, in which the complexity and interdependence of environmental issues were recognized, as well as their occurrence at various geographical scales. Environmental policy and socio-economic policy were considered equally important. Because of ongoing globalization since the early 1990s, more emphasis was put on the importance of the competitiveness of the Dutch economy, and on the notion that a stringent environmental policy might lead to relocation of labour to other countries. This increased awareness that environmental policy should be approached internationally. In the 1990s, concepts such as eco-efficiency and decoupling came into use. Later on, it was recognized that the existing policy was inadequate, and that system innovation was needed. This called for innovation in policy and new institutions.
